## 1.1 Motivation

Motivating example: Suppose we want to describe where the gas molecules are in a room.

Approach 1: Label every gas molecule and give  $x, y, z$  coordinates for each.

- Too much data.

Approach 2: Divide the room up into small volumes (boxes). Count the number of molecules in each volume.

- Number of molecules depends on the size of the box
- Take density/concentration:

$$\frac{\# \text{ molecules in the box}}{\text{volume of the box}}$$

We assume the distribution of molecules obeys the Continuum Hypothesis.

We assume our box sizes are in a region in which the number of molecules or volume, so density is well-defined. We defined. We define a **field**  $u(\mathbf{x}, t)$  that describes the density of molecules.

At each point  $u$  counts molecules at  $(\mathbf{x}, t)$ ; in the sense that if I make a box, volume  $dV$ , at  $(\mathbf{x}, t)$ ; the number of molecules in box is:  $u(\mathbf{x}, t)dV$ .

**Note 1.1:**  $u$  is dependent variable, and there are multiple independent variables;  $x, y, z, t$

$u$  (density) is one example of a field - a dependent variable that is defined at different points:

$$u: \mathbb{R}^3 \subset D \times \underbrace{[0, T]}_{\text{time interval}} \rightarrow \mathbb{R}$$

$$u: (\mathbf{x}, t) \mapsto u(\mathbf{x}, t)$$

Other examples:

- Velocity (vector field);  $\mathbf{v}: D \times [0, T] \rightarrow \mathbb{R}^3$
- temperature (scalar field);  $\theta: D \times [0, T] \rightarrow \mathbb{R}$
- Electric field/magnetic field
- Distribution/density of cars
- Displacement of the ocean surface

We will derive (and solve) Partial Differential Equations (PDEs) as mathematical models for scalar and vector fields that depend on position (and in many cases, time).

## 1.2 Example of a PDE

We are modeling the density/distribution of cars on a freeway (looking at only one direction).

Count number of cars in some length  $\ell$  of freeway.

$$\text{density of cars} = \frac{\# \text{ in length } \ell}{\ell}$$

e.g. if  $\ell = 1 \text{ km}$ ; and 1 count 30 cars  $\implies u = 30/\text{km}$  given this density.

If  $\ell = 500\text{m}$ ,

$$\begin{aligned} \# &= 30 \text{ km} \times 500 \text{ m} \\ &= 30/\text{km} \times 0.5 \text{ km} \\ &= 15 \text{ cars} \end{aligned}$$

$u \equiv u(x, t)$ ;  $u$  depends on  $x$  (distance along freeway) and  $t$  (time).

I will assume (Continuum-Hypothesis) that densities calculated at each poinn in the freeway give rise to a  $C^1$  (continuously differentiable) field  $u$ . I want to derive an equation for  $u$ .

Calculus idea: If I know  $u(x, t)$ , I want to calculate the density shortly after;  $u(x, t + \Delta t)$ . If I can do this then I can calculate  $u(x, t + 2\Delta t), u(x, t + 3\Delta t), \dots$ . Imagine that all cars drive at the same speed,  $c$ . Consider  $\#$  cars in some interval.

At time  $t$ , there are  $u(x_0, t)\Delta x$  cars in the interval.

$$\begin{aligned} \# \text{ cars at time } t + \Delta t = & \# \text{ cars at time } t + \# \text{ entering at } x_0 - \Delta x/2 \\ & - \# \text{ leaving at } x_0 + \Delta x/2 \end{aligned}$$

This is the word statement of conservation of mass/cars.

## 2 Mar 30, 2022

### 2.1 Example of a PDE (Cont'd)

#### Recall 2.1

$$\begin{aligned} \# \text{ cars at time } t + \Delta t &= \# \text{ cars at time } t + \# \text{ entering at } x_0 - \Delta x/2 \\ &\quad - \# \text{ leaving at } x_0 + \Delta x/2 \end{aligned}$$

Therefore,

$$u(x_0, t + \Delta t)\Delta x = u(x_0, t)\Delta x + \underline{\hspace{2cm}}$$

Let's fill in the # cars entering or leaving.

Consider station at  $x = x_0 + \Delta x/2$ , how many cars pass this station in time  $\Delta t$ ?

All of the cars to my left, that are within distance  $c\Delta t$  of me, will pass in time  $\Delta t$ . In time  $\Delta t$  a car travels distance  $c\Delta t$ , so # cars in the interval is

$$\underbrace{u(x_0 + \Delta x/2, t)}_{\text{density}} \times \underbrace{c\Delta t}_{\text{length}}$$

We will show it doesn't change anything if we use  $u(x_0 + \frac{\Delta x}{2} - \frac{1}{2}c\Delta t, t)$  instead.

Returning to conservation of cars:

$$\begin{aligned} u(x_0, t + \Delta t)\Delta x &= u(x_0, t)\Delta x + \underbrace{u(x_0 - \Delta x/2, t)c\Delta t}_{\# \text{ entering}} - \underbrace{u(x_0 + \Delta x/2, t)c\Delta t}_{\# \text{ leaving}} \\ (u(x_0, t + \Delta t) - u(x_0, t))\Delta x &= -(u(x_0 + \Delta x/2, t) - u(x_0 - \Delta x/2, t))c\Delta t \end{aligned} \quad (2.1)$$

Recall

$$\frac{\partial u}{\partial t}(x, t) = \lim_{h \rightarrow 0} \left( \frac{u(x, t + h) - u(x, t)}{h} \right)$$

So,

$$\begin{aligned} \frac{\partial u}{\partial x}(x, t) &= \lim_{h \rightarrow 0} \left( \frac{u(x + h, t) - u(x, t)}{h} \right) \\ &= \lim_{h \rightarrow 0} \left( \frac{u(x + h/2, t) - u(x - h/2, t)}{h} \right) \end{aligned}$$

Now dividing (2.1) by  $\Delta x \Delta t$

$$\frac{u(x_0, t + \Delta t) - u(x_0, t)}{\Delta t} = -c \left( \frac{u(x_0 + \Delta x/2, t) - u(x_0 - \Delta x/2, t)}{\Delta x} \right)$$

let  $\Delta x \rightarrow 0, \Delta t \rightarrow 0$ , then

$$\begin{aligned} \frac{\partial u}{\partial t} &= -c \frac{\partial u}{\partial x} \\ \frac{\partial u}{\partial t} + c \frac{\partial u}{\partial x} &= 0 \end{aligned} \quad (2.2)$$

$u$  is a dependent variable, it depends on  $x$  and  $t$  as independent variables.

There is also a constant, parameter  $c$ .

**Notation 2.2:** Other notations are used for partial derivatives.

$$\underbrace{u_t + cu_x = 0}_{\text{Strauss}} \quad \text{or} \quad \underbrace{u_{,t} + cu_{,x}}_{\text{Roper}}$$

There are some solutions of (2.2).

$$\begin{aligned} u &= 1 + \frac{1}{2} \sin(x - ct) \\ u &= \frac{1}{2}(x - ct)^2 \\ u &= e^{-x+ct} \end{aligned}$$

We can check these are solutions

$$\begin{aligned} u(x, t) &= e^{-x+ct} \\ \frac{\partial u}{\partial t} &= ce^{-x+ct} \\ \frac{\partial u}{\partial x} &= -e^{-x+ct} \end{aligned}$$

So

$$\frac{\partial u}{\partial t} + c \frac{\partial u}{\partial x} = ce^{-x+ct} + c(-e^{-x+ct}) = 0$$

Compare with ODEs:

$$\frac{dy}{dx} = y$$

has solution  $y(x) = Ce^x$  which has a constant of integration.

## 2.2 Linearity

In ODEs we use initial conditions to find our constants. To solve a PDE completely, we need both the PDE and an auxiliary or side condition. That is, we need either initial conditions or boundary conditions (or both) on  $u$ . (2.2) is an example of a PDE.

### Definition 2.3 (Operator)

Most generally, a PDE takes the form:

$$\mathcal{L}[u] = 0$$

We call  $\mathcal{L}$  an operator.

In this case:

$$\mathcal{L}[u] = \frac{\partial u}{\partial t} + c \frac{\partial u}{\partial x}$$

$\mathcal{L}$  includes derivatives of  $u$ , more derivatives are possible: e.g.:

$$\mathcal{L}[u] = \frac{\partial^2 u}{\partial t^2} - \frac{\partial^2 u}{\partial x^2}$$

**Definition 2.4** (Linear operator)

We say an operator is linear if it has the following properties:

1. If  $\mathcal{L}[u] = 0$  and  $a$  is constant, then  $\mathcal{L}[au] = 0$ .
2. If  $u_1, u_2$  solve the PDE,  $\mathcal{L}[u_1] = 0, \mathcal{L}[u_2] = 0$ , then  $v = u_1 + u_2$  also solves the PDE  $\mathcal{L}[u_1 + u_2] = 0$ .

For (2.2),

$$\begin{aligned}
 \mathcal{L}[u_1 + u_2] &= \frac{\partial}{\partial t}(u_1 + u_2) + c \frac{\partial}{\partial x}(u_1 + u_2) \\
 &= u_{1,t} + u_{2,t} + c(u_{1,x} + u_{2,x}) \\
 &= (u_{1,t} + cu_{1,x}) + (u_{2,t} + cu_{2,x}) \\
 &= \mathcal{L}[u_1] + \mathcal{L}[u_2]
 \end{aligned}$$

**Example 2.5**

Examples of linear versus non-linear PDEs

1.  $\mathcal{L}[u] = u_{,x} + xu_{,y}$  (linear)
2.  $\mathcal{L}[u] = u_{,t} + \underbrace{u_{,xxx}}_{\partial^3 u / \partial x^3}$  (linear)
3.  $\mathcal{L}[u] = u_{,x} + \alpha u_{,y}, \alpha$  is a constant. (linear)
4.  $\mathcal{L}[u] = u_{,x} + \sqrt{x^2 + y^2} e^{-x} u_{,y}$  (linear)
5.  $\mathcal{L}[u] = u_{,x} + \sqrt{x^2 + u^2} u_{,xx}$  (non-linear)

1)

$$\begin{aligned}
 \mathcal{L}[au] &= au_{,x} + xau_{,y} \\
 &= a(u_{,x} + xu_{,y}) \\
 &= a\mathcal{L}[u] \\
 \mathcal{L}[u_1 + u_2] &= (u_1 + u_2)_{,x} + x(u_1 + u_2)_{,y} \\
 &= (u_{1,x} + xu_{1,y}) + (u_{2,x} + xu_{2,y}) \\
 &= \mathcal{L}[u_1] + \mathcal{L}[u_2]
 \end{aligned}$$

The solution of the PDE is a traveling/shifting copy of  $u(x, t)$ ; we call these solutions **traveling waves**.

## 3 Apr 1, 2022

### 3.1 Characteristics

We are studying the PDE:

$$\frac{\partial u}{\partial t} + c \frac{\partial u}{\partial x} = 0 \quad (3.1)$$

Based on our understanding of how cars move, if all travel at same speed  $c$ , then the solution will be a traveling wave. So, if at time  $t = 0$ ,  $u(x, 0) = g(x)$ , we expect  $u(x, t)$  to be the same graph shifted by  $ct$  units to the right.

**Recall 3.1** If  $y = f(x)$  has a certain graph  $y = f(x - a)$  is the same graph shifted by  $a$  to the right.

So

$$u(x, t) = g(x - ct) \quad (3.2)$$

E.g. if  $u(x, 0) = e^{-x}$  then at time  $t$ ,  $u(x, t) = e^{-(x-ct)} = e^{-x+ct}$ . We can check that any function of the form (3.2) solves our PDE.

$$u_{,t} = -cg'(x - ct)$$

$$u_{,x} = (1)g'(x - ct)$$

Hence,

$$u_{,t} + cu_{,x} = -cg' + cg' = 0$$

To understand, mathematically, why (3.1) has traveling wave solutions, we need to study the **advective derivative**.

Given a field  $\theta(x, t)$  derivatives give us information about the rate of change of  $\theta$ . E.g.

$$\frac{\partial \theta}{\partial t} = \text{time rate of change at fixed } x \text{ (Eulerian derivative)}$$

Another derivative comes from sampling  $\theta$  at different points and times (time rate of change according to a moving observer).

Moving observer has a location  $x(t)$ , their rate of change is given by the **advective derivative** or **Lagrangian derivative**

$$\frac{d}{dt} (\theta(x(t), t)) = \underbrace{\frac{\partial \theta}{\partial x} \frac{dx}{dt}}_{\text{new term}} + \underbrace{\frac{\partial \theta}{\partial t}}_{\text{Eulerian derivative}} \quad (3.3)$$

#### Example 3.2

$\theta(x, t)$  is temperature,  $x$  is distance.

$\theta(x, t) = mx + b$  for some  $m$  and  $b$  constants.

Now imagine an observer enters room, and walks along  $x$ , at speed  $v$  so  $\frac{dx}{dt} = v$ . The time rate of change of temperature is

$$\frac{d\theta}{dt} = mv + 0 = mv$$

Compare (3.3)

$$\frac{d\theta}{dt} = \frac{\partial\theta}{\partial t} + \left(\frac{dx}{dt}\right) \frac{\partial\theta}{\partial x}$$

with (3.1)

$$\frac{\partial u}{\partial t} + c \frac{\partial u}{\partial x} = 0$$

(3.1) says that  $\frac{du}{dt} = 0$  if  $\frac{dx}{dt} = c$ . In other words, according to an observer moving at speed  $\frac{dx}{dt} = c$ , the time rate of change is  $\frac{du}{dt} = 0$ . So  $u$  is constant according to this observer.

Suppose we know  $u(x, 0)$ , the initial density. I can draw a space-time diagram.

According to an observer moving at speed  $c$ , the density is constant. Similarly line starting at  $x = x_1$ . These lines called **characteristics** must be level curves / contours / isocontours of  $u(x, t)$ . Using characteristics, we can solve our equation.

Given  $(x, t)$  what is  $u(x, t)$ ?

I need the PDE and some initial condition or boundary condition, suppose I know  $u(x, 0) = g(x)$ .

$(x, t)$ , where I want density, lies on a characteristic, every point on characteristic has the same density.

Follow the characteristic back to the  $x$ -axis  $u(x, t) = u(x_0, 0)$  where  $x_0$  is where the characteristic hits the  $x$ -axis  $u(x, t) = g(x_0)$ .

Given  $(x, t)$ , I need to find  $x_0$ . From the picture,

$$\begin{aligned}(x - x_0) &= ct \\ x_0 &= x - ct\end{aligned}$$

hence

$$u(x, t) = g(x_0) = g(x - ct)$$

## 3.2 Using Characteristics to Solve More PDEs

Method of characteristics solves PDEs by tracing characteristics; lines or curves on which  $u$  is a constant. It can be used to solve PDEs of the form:

$$a(t, x)u_t + b(t, x)u_x = 0$$

where  $a$  and  $b$  are any functions. Or,

$$a(x, y)u_x + b(x, y)u_y = 0$$

**Note 3.3:** Now we are using  $x$  and  $y$  for independent variables.

This is a linear PDE. it is also called **first order** (only one partial derivative in each term). To use it, start with example:

**Example 3.4**

We have

$$au_{,x} + bu_{,y} = 0$$

where  $a, b$  are both constants ( $a, b$  are not both 0). Solution is  $u(x, y)$ .

Assume I know  $u(x, 0)$ .

$$au_{,x} + bu_{,y} = 0 \iff (a, b)^T \cdot \nabla u = 0$$

i.e. the directional derivative of  $u$ , along  $\begin{pmatrix} a \\ b \end{pmatrix}$  is equal to 0, i.e.  $u$  is constant in the direction  $\begin{pmatrix} a \\ b \end{pmatrix}$ .

Characteristics point in the direction of  $\begin{pmatrix} a \\ b \end{pmatrix}$ .

## 4 Apr 4, 2022

### 4.1 Using Characterizations to Solve More PDEs (Cont'd)

For the PDE:

$$au_{,x} + bu_{,y} = 0$$

Method #1: The lines parallel to  $\begin{pmatrix} a \\ b \end{pmatrix}$  are characteristics.

Characteristics are lines  $y = \frac{b}{a}x + c$  where  $c$  is a constant. Hence the characteristics are lines  $ay - bx = ac = C$ . Each value of  $C$  gives a different straight line, and  $u \equiv f(C)$  or  $u \equiv f(ay - bx)$ . Any function  $u \equiv f(ay - bx)$  is a solution of the PDE. E.g.

$$u(x, y) = \sin(ay - bx)$$

$$u(x, y) = (ay - bx)^2$$

Apply the auxiliary condition to find out what  $f$  is.

#### Example 4.1

Solve  $2u_{,x} + 3u_{,y} = 0$  with an auxiliary condition  $u(0, y) = y^3$  ( $u$  is known on the  $x$ -axis). Theory above says

$$u(x, y) = f(2y - 3x)$$

to satisfy the auxiliary condition:

$$\begin{aligned} u(0, y) &= y^3 \\ \implies f(2y) &= y^3 \\ \implies f(z) &= \left(\frac{z}{2}\right)^3 \\ \implies f(y) &= \left(\frac{y}{2}\right)^3 \end{aligned}$$

So

$$u(x, y) = f(2y - 3x) = \left(\frac{2y - 3x}{2}\right)^3$$

Method #2: If we didn't explicitly use the equation of a straight line, we know that the characteristics are parallel to  $\begin{pmatrix} a \\ b \end{pmatrix}$ . If a characteristic is a curve  $(x(s), y(s))$ .

Where,

$$\frac{dx}{ds} = a \quad \frac{dy}{ds} = b$$

Chain rule says

$$\frac{dy}{dx} = \frac{\frac{dy}{ds}}{\frac{dx}{ds}} = \frac{b}{a}$$

Hence,

$$y = \left(\frac{b}{a}\right)x + c$$

We can follow Method #2, even when  $a$  and  $b$  are not constants.

**Example 4.2**

Solve  $u_{,x} + yu_{,y} = 0$  with an auxiliary condition  $u(0, y) = 5y$ .

Our PDE gives:

$$\begin{pmatrix} 1 \\ y \end{pmatrix} \cdot \nabla u = 0$$

which implies  $\nabla u$  is perpendicular to  $\begin{pmatrix} 1 \\ y \end{pmatrix}$ . In other words, I can define characteristics (on which  $u$  is constant) that are always parallel to  $\begin{pmatrix} 1 \\ y \end{pmatrix}$ .

The equation of any characteristic is:

$$\frac{dx}{ds} = 1 \qquad \frac{dy}{ds} = y$$

$$\frac{dy}{dx} = \frac{\frac{dy}{ds}}{\frac{dx}{ds}} = y$$

So the characteristics are lines  $y(x) = Ce^x$ . Different values of  $C$  give different characteristics, and therefore different values of  $u$ .

$$\begin{aligned} u &= f(C) \\ u &= f(ye^{-x}) \end{aligned}$$

$$\implies \begin{cases} u(x, y) = (ye^{-x})^2 \\ u(x, y) = \sinh(ye^{-x}) \end{cases}$$

Appeal to the auxiliary condition

$$u(0, y) = 5y \implies \begin{cases} f(y) = 5y \\ f(z) = 5z \end{cases}$$

Hence,  $u(x, y) = f(ye^{-x}) = 5ye^{-x}$ .

**Example 4.3**

Solve  $y u_{,x} - x u_{,y} = 0$  with auxiliary condition  $u(x, 0) = e^{-x^2}$ .

$u$  is constant on characteristics

$$\left. \begin{array}{l} \frac{dx}{ds} = y \\ \frac{dy}{ds} = -x \end{array} \right\} \Rightarrow \frac{dy}{dx} = \frac{-x}{y}$$

So

$$\begin{aligned} 2 \int y dy &= 2 \int -x dx \\ y^2 &= -x^2 + C \\ \Rightarrow x^2 + y^2 &= C \text{ on characteristics} \end{aligned}$$

So  $u \equiv f(x^2 + y^2)$  and

$$\begin{aligned} u(x, 0) &= f(x^2) = e^{-x^2} \\ f(z) &= e^{-z} \end{aligned}$$

hence  $u(x, y) = e^{-x^2 - y^2}$ .

**Note 4.4:** Each point  $(x, y)$  lies on  $\begin{cases} \text{a characteristic that meets the } x\text{-axis in 2 places} \\ \text{2 characteristics} \end{cases}$ .

This can be a problem for some kinds of auxiliary conditions. E.g. if  $u(x, 0) = e^{-x}$ .

## 4.2 PDE Models

We met

$$\frac{\partial u}{\partial t} + c \frac{\partial u}{\partial x} = 0$$

as an example of conservation of mass. This is an example of a transport model. Other examples start from the following idea:

$$u \text{ changes in an interval } \left( x_0 - \frac{\Delta x}{2}, x_0 + \frac{\Delta x}{2} \right)$$

due to flows at either end of the interval. We model these flows through a field  $q$ .  $q(x, t)$  is the rate at which mass (e.g. cars) pass a station  $x$ .

$$q = \frac{\# \text{ cars} / \text{amount of mass passing } x}{\text{time counted over}}$$

## 5 Apr 6, 2022

### 5.1 PDE Models (Cont'd)

We can think of  $q(x, t)$  as being a new field, governed by the Continuum Hypothesis in the sense that.

Conservation of mass on an interval  $(x_0 - \Delta x/2, x_0 + \Delta x/2)$  gives

$$u(x_0, t + \Delta t) = u(x_0, t) + \text{amount entering at } x = x_0 - \Delta x/2 \\ - \text{amount leaving at } x = x_0 + \Delta x/2 \quad (5.1)$$

By default, I assume positive  $q$  means flow is from left to right.

$$q = \frac{\text{amount flowing left to right} - \text{amount flowing right to left}}{\text{time observed over}}$$

Returning to (5.1):

$$u(x_0, t + \Delta t)\Delta x = u(x_0, t)\Delta x + q\left(x_0 - \Delta\frac{x}{2}, t\right)\Delta t - q\left(x_0 + \Delta\frac{x}{2}, t\right)\Delta t$$

On rearranging, dividing by  $\Delta x \Delta t$  and letting  $\Delta x, \Delta t \rightarrow 0$  we obtain the **Conservation of mass law**:

$$\frac{\partial u}{\partial t} = -\frac{\partial q}{\partial x} \quad (5.2)$$

We arrive at the PDEs of Math 136, typically by starting (5.2) and then doing more modeling to find how  $q$  is related to  $u$ .

**Examples 5.1**

1. Traffic flow with constant speed. Claim that  $q = cu$ .

Amount passing station  $x$  in time  $\Delta t$  is

amt contained in interval of size  $c\Delta t$

$$\begin{aligned} q(x, t)\Delta t &= u\left(x - \frac{1}{2}c\Delta t, t\right) \Delta x \\ &= u\left(x - \frac{1}{2}c\Delta t, t\right) c\Delta t \end{aligned}$$

Now dividing by  $\Delta t$ , let  $\Delta t \rightarrow 0$ .

$$\begin{aligned} q(x, t) &= \lim_{\Delta t \rightarrow 0} \left[ cu\left(x - \frac{1}{2}c\Delta t, t\right) \right] \\ &= cu(x, t) \end{aligned}$$

2. Lighthill - Whitham Richards model for traffic flow.

$$q(x, t) = c(u)u(x, t)$$

that is, the velocity of cars depends on how dense the traffic is.

(1) and (2) both may be written as a PDE

$$\begin{aligned} \frac{\partial u}{\partial t} + \frac{\partial q}{\partial x} &= 0 \\ \implies \frac{\partial u}{\partial t} + \frac{\partial}{\partial x} \overbrace{c \cdot u}^q &= 0 \end{aligned}$$

In (1)

$$\frac{\partial u}{\partial t} + c \frac{\partial u}{\partial x} = 0$$

In (2)

$$\frac{\partial u}{\partial t} + \frac{dq}{du} \cdot \frac{\partial u}{\partial x} = 0$$

More examples,

**Example 5.2** 1. Random motion or diffusion.

A lot of matter moves around randomly. E.g. bacteria swimming around.

Follow random “run & tumble” paths. Consider a pair of linked boxes.

more flow left-to-right if  
more bacteria in left box

We expect the flow to take bacteria on net out of regions where they are very dense/concentrated into regions where they are sparse/dilute. We posit that

$$q \propto -\frac{\partial u}{\partial x} \quad (\text{Fick's Law})$$

flow is right to left  
 $q < 0$

flow is bigger when  $\left| \frac{\partial u}{\partial x} \right|$  is bigger

$$q = -D \frac{\partial u}{\partial x}$$

$D$ , the constant of proportionality is known as the **diffusivity**.

Consider units:

$$[u] = \# / m$$

$$[q] = \# / s$$

$$\left[ \frac{\partial u}{\partial x} \right] = \frac{[u]}{[x]} = \# / m^2$$

$$[D] = \left[ -\frac{q}{\frac{\partial u}{\partial x}} \right] = \frac{\# / s}{\# / m^2} = m^2 / s$$

Hence matter that is diffusing obeys a PDE

$$\frac{\partial u}{\partial t} + \frac{\partial q}{\partial x} = 0$$

$$\frac{\partial u}{\partial t} + \frac{\partial}{\partial x} \left( -D \frac{\partial u}{\partial x} \right) = 0$$

$$\frac{\partial u}{\partial t} - D \frac{\partial^2 u}{\partial x^2} = 0 \quad (5.3)$$

assume  $D$  is a constant. This is a second order linear equation called the **diffusion equation** / **heat equation**.

We often are interested in quantities with multiple space-dimensions. Define  $u$  density per volume.

$u(\mathbf{x}, t) dV =$  amount of matter in a small volume,  $dV$  located at  $(\mathbf{x}, t)$

$q(\mathbf{x}, t) \cdot \mathbf{n} dS =$  flow of matter across an element of surface, area  $dS$

## 6 Apr 8, 2022

### 6.1 PDE Models (Cont'd)

We introduce a vector field  $q(\mathbf{x}, t)$ . Vector  $q$  represents the amount of flow of matter at a point  $\mathbf{x}$ . Vector  $q$  gives how much flow crosses a surface  $\mathbf{n}dS$  in time  $\Delta t$  as

$$q(\mathbf{x}, t) \cdot \mathbf{n}dS\Delta t.$$

This is the net flow from the  $\ominus$  side to the  $\oplus$  side.

Amount of flow through surface is proportional to  $dS$  (area) and is proportional to  $\Delta t$  (time of observation).

To derive a PDE for conservation of mass, consider an arbitrary volume (called control volume)  $\Omega$ , with piecewise differentiable and orientable boundary  $\partial\Omega$ , consider conservation of mass in  $\Omega$ .

Total amount of matter in  $\Omega$  is  $\int u \cdot dV$  (divide  $\Omega$  into boxes  $dV$ , amount in each box is  $u(\mathbf{x}, t)dV$ , sum up boxes and take  $dV \rightarrow 0$ ). Change in matter in time  $t \rightarrow \Delta t$  is

$$\int_{\Omega} u(\mathbf{x}, t + \Delta t) dV = \int_{\Omega} u(\mathbf{x}, t) dV + \text{amt gained by flow through } \partial\Omega$$

(+ amt of matter created – amt of matter destroyed)

Divide boundary into surface elements  $\mathbf{n}dS$ . Flow through surface element in time  $\Delta t$  is

$$q(\mathbf{x}, t) \cdot \mathbf{n}dS\Delta t.$$

Total flow out of  $\Omega$  (assuming  $\mathbf{n}$  points out of  $\Omega$ ) through entire of  $\partial\Omega$  is

$$\int_{\partial\Omega} q(\mathbf{x}, t) \cdot \mathbf{n} dS \Delta t$$

summing all surface elements and letting  $dS \rightarrow 0$ . Amount gained in time  $\Delta t$  is:

$$- \int_{\partial\Omega} q(\mathbf{x}, t) \cdot \mathbf{n} dS \Delta t$$

Hence,

$$\int_{\Omega} (u(\mathbf{x}, t + \Delta t) - u(\mathbf{x}, t)) dV = - \int_{\partial\Omega} q(\mathbf{x}, t) \cdot \mathbf{n} dS \Delta t$$

Divide by  $\Delta t$ ,

$$\int_{\Omega} \frac{(u(\mathbf{x}, t + \Delta t) - u(\mathbf{x}, t))}{\Delta t} dV = - \int_{\partial\Omega} q(\mathbf{x}, t) \cdot \mathbf{n} dS$$

let  $\Delta t \rightarrow 0$ ,

$$\begin{aligned} \int_{\Omega} \frac{\partial u}{\partial t} dV &= - \int_{\partial\Omega} q(\mathbf{x}, t) \mathbf{n} dS \\ &= - \int_{\Omega} \nabla \cdot \mathbf{q} dV \end{aligned}$$

Use divergence theorem so that both sides are same type of integral. Now,

$$\int_{\Omega} \left( \frac{\partial u}{\partial t} + \nabla \cdot \mathbf{q} \right) dV = 0$$

This integral vanishes for any choice of  $\Omega$ , so the integrand must be 0. Hence

$$\frac{\partial u}{\partial t} + \nabla \cdot \mathbf{q} = 0 \tag{6.1}$$

everywhere. In 1D,

$$\frac{\partial u}{\partial t} + \frac{\partial q}{\partial x} = 0$$

To turn this into a PDE we can solve, we need to do additional modeling on  $\mathbf{q}$ .

**Recall 6.1** The diffusion equation in 1D said

$$q = -D \frac{\partial u}{\partial x}$$

in  $n$  dimensions, visualize  $u$  through level surfaces.  $q \propto -\nabla u$  (Fick's Law)

So

$$\begin{aligned} q &= -D \nabla u \\ \implies \frac{\partial u}{\partial t} + \nabla \cdot (-D \nabla u) &= 0 \end{aligned}$$

from (6.1)

$$\frac{\partial u}{\partial t} - D \nabla \cdot (\nabla u) \equiv \frac{\partial u}{\partial t} - D \nabla^2 u = 0 \quad (6.2)$$

which is the **diffusion/heat equation**.

We are often interested in the steady state / equilibrium distribution of matter, in (6.2) we may consider what happens when  $\frac{\partial u}{\partial t} = 0$ , then

$$-D \nabla^2 u = 0 \quad \text{i.e.} \quad -\nabla^2 u = 0 \quad (6.3)$$

called **Laplace's equation**.

## 6.2 Wave Equation

Imagine a plucked string.

The string vibrates, define a field  $u(x, t)$  that measures the displacement of the string (assumed planar). Consider a force balance on a piece of string of length  $\Delta x$ .

If the mass of unit length of string is  $\rho$ , then the mass of  $\Delta x$  length is  $\rho\Delta x$ .

mass  $\times$  acceleration = net force

$$\begin{aligned}\rho\Delta \frac{\partial^2 u}{\partial t^2} &= T \sin \theta(x + \Delta x/2, t) - T \sin \theta(x - \Delta x/2, t) \\ &= T \frac{\partial}{\partial x} \sin \theta \cdot \Delta x\end{aligned}$$

$\theta$  is the angle between the tension in the string and the  $x$ -axis,  $\theta(x, t)$  is a field, so at each point  $T$  points along the tangent direction.

The string is at  $(x, u(x, t))$  so the tangent vector is

$$\mathbf{t} = \frac{(1, \frac{\partial u}{\partial x})}{\sqrt{1 + \left(\frac{\partial u}{\partial x}\right)^2}}$$

Geometrically,

$$\sin \theta = \frac{\frac{\partial u}{\partial x}}{\sqrt{1 + \left(\frac{\partial u}{\partial x}\right)^2}}$$

which is approximately  $\frac{\partial u}{\partial x}$  if  $\left(\frac{\partial u}{\partial x}\right)^2 \ll 1$  (small slope)

$$\rho\Delta x \frac{\partial^2 u}{\partial t^2} = T \frac{\partial}{\partial x} \sin \theta \Delta x$$

$$\frac{\partial^2 u}{\partial t^2} = \left(\frac{T}{\rho}\right) \frac{\partial^2 u}{\partial x^2} \quad (6.4)$$

Which is the **wave equation**.

# 7 Apr 11, 2022

## 7.1 Wave Equation (Cont'd)

**Note 7.1:** Notes on the wave equation:

$$\frac{\partial^2 u}{\partial t^2} = \frac{T}{\rho} \frac{\partial^2 u}{\partial x^2}$$

for

$$u: \mathbb{R} \times \mathbb{R} \rightarrow \mathbb{R} \\ (x, t) \mapsto u(x, t)$$

or equivalently,

$$u_{,tt} = c^2 u_{,xx} \quad \text{where} \quad c = \sqrt{\frac{T}{\rho}}$$

is the **wave speed**. Consider units:

$$\begin{aligned} [u_{,tt}] &= ms^{-2} \\ [u_{,xx}] &= \frac{m}{m^2} = m^{-1} \\ \implies [c^2] &= \left[ \frac{u_{,tt}}{u_{,xx}} \right] = \frac{ms^{-2}}{m^{-1}} = (ms^{-1})^2 \end{aligned}$$

$c$  has units of velocity.

**Note 7.2:** In  $\mathbb{R}^n$ ,  $u \equiv u(\mathbf{x}, t)$ , the wave equation is

$$u_{,tt} = c^2 \nabla^2 u (\equiv c^2 \Delta u)$$

where  $\nabla^2$  is the Laplacian. (see Math 272A)

**Note 7.3:** Compare Wave Equation and Diffusion Equation.  $u(\mathbf{x}, t)$  solves

$$u_{,t} = D \nabla^2 u \quad (\text{Diffusion})$$

$$u_{,tt} = c^2 \nabla^2 u \quad (\text{Wave})$$

## 7.2 Summary

Transport PDE:

$$\begin{aligned} u_{,t} + \nabla \cdot (\mathbf{c}u) &= 0 \\ \text{in } \mathbb{R}^1 \quad u_{,t} + \frac{\partial}{\partial x}(\mathbf{c}u) &= 0 \end{aligned}$$

Diffusion equation:

$$u_{,t} = D \nabla^2 u$$

Wave equation:

$$u_{,tt} = c^2 \nabla^2 u$$

In both diffusion equation and heat equation, if the system reaches equilibrium, then:

$$-\nabla^2 u = 0 \quad (\text{Laplace's equation})$$

Each equation can have forcing or reaction terms added to it. E.g. in the diffusion equation, we start with:

$$u_{,t} + \nabla \cdot \mathbf{q} = 0 \quad (\text{conservation of mass})$$

(in homework # 3) we will add a reaction/source term.

$$u_{,t} + \nabla \cdot \mathbf{q} = s$$

$s$  is the function representing creation of new matter.  $s(\mathbf{x}, t)dV$  is the amount of new matter created in volume  $dV$  in one unit of time. Diffusion equation may become:

$$u_{,t} - D\nabla^2 u = s(\mathbf{x}, t)$$

which  $s$  is some function. This is the **forced diffusion equation**. In the equilibrium limit:

$$-\nabla^2 u = \frac{s(\mathbf{x}, t)}{D}$$

which is **forced Laplace's equation** or **Poisson's equation**.

## 7.3 Auxiliary Conditions

For first order PDEs, we need to know  $u$  on some lines in space time, i.e. we need some initial condition or we need some boundary conditions or both.

### Example 7.4

If we are solving a model for traffic flow on  $0 < x < L$  then we need

$$u(x, 0) \quad (\text{IC})$$

and either

$$u(0, t) \quad \text{or} \quad u(L, t) \quad (\text{BC})$$

**Example 7.5**

Given the diffusion equation:

$$u_t = D \frac{\partial^2 u}{\partial x^2} \quad \text{on } 0 < x < L$$

We need  $u(x, 0)$  and  $\left. \begin{matrix} u(0, t) \\ \frac{\partial u}{\partial x}(0, t) \end{matrix} \right\}$  or  $\left. \begin{matrix} u(L, t) \\ \frac{\partial u}{\partial x}(L, t) \end{matrix} \right\}$  or.

We need either need the density at the boundary or the flux there.

$$q = -D \frac{\partial u}{\partial x}$$

What do bacteria do when they arrive at  $x = 0$ ?

Possibility # 1: Bacteria leave; (become extremely dilute)

$$u(0, t) = 0$$

which is the **Dirichlet boundary condition**

Possibility # 2: End of tube is sealed.

Bacteria reaching end of tube reverse course. Since There is no net flow from right to left or conversely

$$q(0, t) = 0$$

$$-D \frac{\partial u}{\partial x}(0, t) = 0$$

which is the **Neumann boundary condition**.

## 7.4 Main Types of 2nd Order Linear PDE

There are 3 main types of 2nd order linear PDE:

1. **Elliptic**
2. **Parabolic** and
3. **Hyperbolic**

We restrict to PDEs in 2 variables

$$u(x, y)$$

solves

$$a_{11}(x, y)u_{,xx} + 2a_{12}u_{,xy} + a_{22}u_{,yy} + u_{,yy} \\ \left( + \text{first order and 0th order terms} \right) \\ \text{e.g. } c_1u_{,x} + c_2u_{,y}$$

We can rewrite our PDE as

$$0 = a_{11} \left( \frac{\partial}{\partial x} + \frac{a_{12}}{a_{11}} \frac{\partial}{\partial y} \right)^2 u + \left( a_{22} - \frac{a_{12}^2}{a_{11}} \right) \frac{\partial^2 u}{\partial y^2} \\ = a_{11} \left( \frac{\partial^2}{\partial x^2} + \frac{2a_{12}}{a_{11}} \frac{\partial^2}{\partial x \partial y} + \frac{a_{12}^2}{a_{11}^2} \frac{\partial^2}{\partial y^2} + \text{first \& 0th order terms} \right)$$

If we do the right change of variables, we rewrite our PDE as:

$$0 = \frac{\partial^2}{\partial x^2} u + \left( a_{22} - \frac{a_{12}^2}{a_{11}} \right) \frac{\partial^2 u}{\partial y^2} + \text{other terms}$$

Wave equation: in  $\mathbb{R} \times \mathbb{R}$

$$u_{,xx} - \frac{u_{,tt}}{c^2} = 0$$

Laplace's equation: in  $\mathbb{R}^2$

$$u_{,xx} + u_{,yy} = 0$$

So,

**Definition 7.6** (Hyperbolic vs. elliptic vs. parabolic)

If

$$a_{22} - \frac{a_{12}^2}{a_{11}} < 0 \iff a_{12}^2 > a_{11}a_{22}$$

then our transformed equation looks like the wave equation. We call it hyperbolic.

If

$$a_{22} - \frac{a_{12}^2}{a_{11}} > 0 \iff a_{12}^2 < a_{11}a_{22}$$

then it looks like Laplace's equation. We call it elliptic.

If

$$a_{12}^2 = a_{11}a_{22}$$

then it looks like

$$D \frac{\partial^2 u}{\partial x^2} - u_{,t} = 0$$

the diffusion equation, we call it parabolic.

## 7.5 Wave Equation

Wave equation in 1D has the form:

$$u_{,tt} = c^2 u_{,xx}$$

In Homework 2, you showed a special case of the formula that:

$$u(x, t) = f(x - ct) + g(x + ct)$$

solves this PDE for any twice differentiable  $f$  and  $g$ . Solution is made up of two traveling waves, one going left at speed  $c$  and one going right at speed  $c$ .

## 8 Apr 13, 2022

### 8.1 Return to the Wave Equation and d'Alembert's Solution

Consider the wave equation on the real line

$$u_{,tt} = c^2 u_{,xx}, \quad -\infty < x < \infty$$

Typically, our auxilliary conditions take the form of initial conditions on  $u$  and  $u_t$  (starting position and starting velocity)

$$u(x, 0) = \phi(x)$$

$$u_t(x, 0) = \psi(x)$$

Rewrite the wave equation as

$$\begin{aligned} \left( \frac{\partial^2}{\partial t^2} - c^2 \frac{\partial^2}{\partial x^2} \right) u &= 0 \\ \left( \frac{\partial}{\partial t} - c \frac{\partial}{\partial x} \right) \left( \frac{\partial}{\partial t} + c \frac{\partial}{\partial x} \right) u &= 0 \\ \left( \frac{\partial}{\partial t} + c \frac{\partial}{\partial x} \right) u = 0 &\iff u = f(x - ct) \\ \left( \frac{\partial}{\partial t} - c \frac{\partial}{\partial x} \right) u = 0 &\iff u = g(x + ct) \end{aligned}$$

Because the operators commute,

$$u = f(x - ct) + g(x + ct)$$

A second, slower but clearer, route to the same form of solution is to make a transformation of coordinates.

$$(x, t) \mapsto (\xi, \eta)$$

where

$$\begin{cases} \xi = x - ct \\ \eta = x + ct \end{cases} \quad \text{and} \quad \begin{cases} x = \frac{1}{2}(\xi + \eta) \\ t = \frac{1}{2c}(\eta - \xi) \end{cases}$$

I will rewrite the PDE in terms of  $\xi$  and  $\eta$ .

$$\begin{aligned} \left( \frac{\partial}{\partial t} \right)_x &= \left( \frac{\partial \xi}{\partial t} \right)_x \left( \frac{\partial}{\partial \xi} \right)_\eta + \left( \frac{\partial \eta}{\partial t} \right)_x \left( \frac{\partial}{\partial \eta} \right)_\xi \quad \text{by the Chain Rule} \\ &= -c \left( \frac{\partial}{\partial \xi} \right)_\eta + c \left( \frac{\partial}{\partial \eta} \right)_\xi \\ \left( \frac{\partial}{\partial x} \right)_t &= \left( \frac{\partial \xi}{\partial x} \right)_t \left( \frac{\partial}{\partial \xi} \right)_\eta + \left( \frac{\partial \eta}{\partial x} \right)_t \left( \frac{\partial}{\partial \eta} \right)_\xi \\ &= (1) \left( \frac{\partial}{\partial \xi} \right)_\eta + (1) \left( \frac{\partial}{\partial \eta} \right)_\xi \end{aligned}$$

So,

$$\begin{aligned}\frac{\partial^2 h}{\partial t^2} &= c^2 \left( -\frac{\partial}{\partial \xi} + \frac{\partial}{\partial \eta} \right)^2 h \\ &= c^2 \left( \frac{\partial^2 h}{\partial \xi^2} - \frac{2\partial^2 h}{\partial \xi \partial \eta} + \frac{\partial^2 h}{\partial \eta^2} \right) \\ \frac{\partial^2}{\partial x^2} &= \left( \frac{\partial}{\partial \xi} + \frac{\partial}{\partial \eta} \right)^2 \\ &= \frac{\partial^2}{\partial \xi^2} + \frac{2\partial^2}{\partial \xi \partial \eta} + \frac{\partial^2}{\partial \eta^2}\end{aligned}$$

Hence

$$\frac{\partial^2 u}{\partial t^2} - c^2 \frac{\partial^2 u}{\partial x^2} = -4 \frac{c^2 \partial^2 u}{\partial \xi \partial \eta} = 0$$

i.e.

$$\frac{\partial^2 u}{\partial \xi \partial \eta} = 0$$

which can be integrated

$$\begin{aligned}\frac{\partial u}{\partial \eta} &= A(\eta) \\ &= g(\eta) + f(\xi)\end{aligned}$$

where  $f$  and  $g$  are both arbitrary functions.

$$u(x, t) = f(x - ct) + g(x + ct) \quad (8.1)$$

is the only solutions, called **d'Alembert's solution**. Any solution of the wave equation is made up of two traveling waves, one with speed  $c$ , and one with speed  $-c$ .

We can choose  $f$  and  $g$  to satisfy the initial conditions.

$$u(x, 0) = \phi(x)$$

From (8.1)

$$f(x) + g(x) = \phi(x) \quad (8.2)$$

$$u_{,t}(x, 0) = \psi(x)$$

from (8.1),

$$-cf'(x) + cg'(x) = \psi(x) \quad (8.3)$$

Solve (8.2) and (8.3) for  $f$  and  $g$ . (8.2) implies

$$f'(x) + g'(x) = \psi'(x)$$

$$2cg'(x) = c\phi'(x) + \psi(x)$$

$$2cf'(x) = c\phi'(x) - \psi(x)$$

So

$$f(\xi) = \frac{1}{2}\phi(\xi) - \frac{1}{2c} \int_0^\xi \psi(y) dy + A$$

$$g(\eta) = \frac{1}{2}\phi(\eta) + \frac{1}{2c} \int_0^\eta \psi(y) dy + B$$

where  $A$  and  $B$  are constants of integration. Now what are  $A$  and  $B$ ? Substitute into (8.2)

$$f(x) + g(x) = \phi(x)$$

$$\left( \frac{1}{2}\phi(x) - \frac{1}{2c} \int_0^x \psi(y) dy + A \right) + \left( \frac{1}{2}\phi(x) + \frac{1}{2c} \int_0^x \psi(y) dy + B \right) = \phi(x)$$

And so  $A + B = 0$ . So

$$u(x, t) = f(\xi) + g(\eta)$$

so  $A + B$  cancels. So

$$u(x, t) = \frac{1}{2}\phi(x - ct) - \frac{1}{2c} \int_0^{x-ct} \psi(y) dy + A + \frac{1}{2}\phi(x + ct) + \frac{1}{2c} \int_0^{x+ct} \psi(y) dy + B$$

$$u(x, t) = \frac{1}{2}(\phi(x - ct) + \phi(x + ct)) + \frac{1}{2c} \int_{x-ct}^{x+ct} \psi(y) dy$$

which is **d'Alembert's solution**.

### Example 8.1 (3 finger pluck)

infinitely long string has initial shape  $\phi$  and  $\psi = 0$ , what is  $u(x, t)$

**Example 8.2** (Hammer punch)

Let  $c = 1$ .

$$u(x, 0) = 0, u_t(x, 0) = \begin{cases} 1 & \text{if } |x| < 1. \\ 0 & \text{otherwise} \end{cases}$$

## 9 Apr 15, 2022

### 9.1 D'Alembert's Formula

By d'Alembert's formula,

$$\begin{aligned}
 u &= \underbrace{0}_{\phi \text{ part}} + \frac{1}{2} \int_{x-ct}^{x+ct} \psi dy \\
 &= \frac{1}{2} \text{length} \{ (x-ct, x+ct) \cap (-1, 1) \}
 \end{aligned}$$

$$u = \frac{1}{2c} \times (\text{length of interval above } \psi = 1 \text{ and that is contained in the domain of dependence})$$

We will discuss the geometry in D'Alembert's formula, and then return to the hammer punch example.

$\phi$  part of solution depends on values of  $u(x-ct, 0)$  and  $u(x+ct, 0)$ .

$\psi$  part of solution depends on values of  $u_t(y, 0)$  for  $x-ct < y < x+ct$ . In totality,  $u(x, t)$  depends on initial condition information only between  $x-ct$  and  $x+ct$ .

**Definition 9.1** (Domain of dependence)

We call the region where the initial condition matters/ can affect  $(x, t)$  the domain of dependence.

As  $t$  increases, domain of dependence expands at speed  $\pm c$ .

The wave equations have a **causality principle**. Info about an initial condition or a change in  $u$ , can not travel faster than  $\pm c$ .

Suppose I pluck the string at  $(x_0, t_0)$ , this can only affect  $u(x, t)$  within a triangle of space-time that expands at speed  $\pm c$ .

Call this triangle the **region of influence**.

**Recall 9.2**  $c^2 = T/\rho$ .

Causality is particularly insightful when our initial conditions on  $(\phi$  and  $\psi)$  are both compactly supported, i.e.  $\phi, \psi$  are both non-zero only within a finite interval/finite set of finite intervals (see homework).

## 9.2 Energy in the Wave Equation

The wave equation was defined as a model for a stretched string that is vibrating.

We considered force balances, now we will consider energy. The element of string has two types of energy:

- Kinetic (movement)
- Potential (stored in stretching of string)

$$KE = \underbrace{\rho \Delta x}_{\text{mass}} \times \underbrace{\left( \frac{\partial u}{\partial t} \right)^2}_{\text{velocity sq'd}}$$

$$PE = \text{force applied} \times \text{amount of displacement (how far it stretches)}$$

$$\begin{aligned}
\Delta u &= u(x_0 + \Delta x/2, t) - u(x_0 - \Delta x/2, t) \\
&= \frac{\partial u}{\partial x}(x_0, t) \Delta x \quad \text{assuming small } \Delta x \\
\text{stretch} &= \sqrt{\Delta x^2 + \Delta u^2} - \Delta x \\
&= \Delta x \sqrt{1 + \left(\frac{\partial u}{\partial x}\right)^2} - \Delta x
\end{aligned}$$

We assumed, to derive the wave equation, that  $\left|\frac{\partial u}{\partial x}\right| \ll 1$ . Hence,

$$\begin{aligned}
\text{stretch} &\approx \Delta x \left(1 + \frac{1}{2} \left(\frac{\partial u}{\partial x}\right)^2 + \cdots\right) - \Delta x \\
&= \frac{1}{2} \Delta x \left(\frac{\partial u}{\partial x}\right)^2
\end{aligned}$$

The total energy is:

$$\frac{1}{2} (\rho u_{,t}^2 + T u_{,x}^2) \Delta x \quad \text{for an element of length } \Delta x$$

So the total energy of the entire string is:

$$E = \frac{1}{2} \int_{\text{length of string}} (\rho u_{,t}^2 + T u_{,x}^2) dx$$

summing the element contributions and letting  $\Delta x \rightarrow 0$ .

$$\frac{E}{\rho} = \frac{1}{2} \int_{\text{length of string}} (u_{,t}^2 - c^2 u_{,x}^2) dx$$

We believe that  $E$  (and  $E/\rho$ ) are conserved i.e. stay constant over time.

**Claim:** If  $u$  solves the 1D wave equation:

$$u_{,tt} + c^2 u_{,xx}$$

and our initial conditions are such that

$$E = \frac{1}{2} \int_{-\infty}^{\infty} (u_{,t}^2 + c^2 u_{,x}^2) dx < \infty$$

then  $E$  is a constant.

**Proof.**

$$\begin{aligned}
\frac{dE}{dt} &= \frac{1}{2} \frac{d}{dt} \int_{-\infty}^{\infty} (u_{,t}^2 + c^2 u_{,x}^2) dx \\
&= \frac{1}{2} \int_{-\infty}^{\infty} \frac{\partial}{\partial t} (u_{,t}^2 + c^2 u_{,x}^2) dx
\end{aligned}$$

by generalized Leibniz/FTC

$$\begin{aligned} &= \int_{-\infty}^{\infty} (u_t u_{,tt} + c^2 u_{,x} u_{,xt}) dx \\ &= \int_{-\infty}^{\infty} u_t u_{,tt} dx + c^2 [u_{,x} u_{,t}]_{-\infty}^{\infty} \end{aligned}$$

Use integration by parts

$$-c^2 \int_{-\infty}^{\infty} u_{,xx} u_{,t} dx$$

We continue this proof in the next lecture.

□

## 10.1 Energy in the Wave Equation (Cont'd)

**Cont'd.** We used integration by parts:

$$\tilde{u}v'dx = [\tilde{u}v] - \int \tilde{u}'vdx$$

let  $\begin{cases} \tilde{u} = u_{,x} \\ v = u_{,xt} \end{cases}$  to apply this formula. For  $E$  to be a finite integral, we need its integrand

$$u_{,t}^2 + c^2 u_{,x}^2 \rightarrow 0 \quad \text{as } x \rightarrow \pm\infty$$

i.e.

$$u_{,t}^2 \rightarrow 0 \quad \text{and} \quad u_{,x}^2 \rightarrow 0$$

So the boundary term

$$[u_{,x}u_{,t}]_{-\infty}^{\infty} = 0$$

Hence,

$$\frac{dE}{dt} = \int_{-\infty}^{\infty} u_{,t} \underbrace{(u_{,tt} - c^2 u_{,xx})}_{\text{wave eq'n says } =0} dx$$

Hence:

$$\frac{dE}{dt} = 0$$

So  $E$  is a constant. □

Having a conserved energy gives us some insight into the wave equation and its solutions.

1. It is impossible if  $u, u_{,t}$  are not both 0 at  $t = 0$ , for  $u \rightarrow 0$  as  $t \rightarrow \infty$ .

Because unless  $E = 0$  at  $t = 0$ , it can not approach 0.

A real guitar string loses energy over time.

- Friction
- Energy is radiated as sound waves

2. Energy arguments can be used to show the solutions of the wave equation are unique.  
In general, differential equations may not have unique solutions.

$$\frac{dy}{dx} = y^{1/2}, \quad y(0) = 0$$

has solution  $y(x) = 0$  and

$$\begin{aligned}\int \frac{1}{y^{1/2}} dy &= \int dx \\ 2y^{1/2} &= x + C \\ y^{1/2} &= \frac{1}{4}(x + C) = \frac{1}{4}x^2\end{aligned}$$

on applying the initial condition.

In models of the real world, we want solutions to be unique, i.e. the model predicts specifically only one possible “fate”/future set of behaviors. Energy arguments can show uniqueness.

**Example 10.1**

If

$$\begin{aligned}u_{,tt} &= c^2 u_{,xx} \\ u(x, 0) &= \phi(x) \\ u_{,t}(x, 0) &= \psi(x)\end{aligned}$$

are the initial conditions, there is at most one solution  $u$ , to this equation.

**Proof:** Suppose we have two solutions  $u_1, u_2$ .

$$u_{1,tt} = c^2 u_{1,xx} \quad \text{and} \quad u_1(x, 0) = \phi, \quad u_{1,t}(x, 0) = \psi$$

$$u_{2,tt} = c^2 u_{2,xx}$$

Let  $w \equiv u_1 - u_2$ .

$$\begin{aligned}w_{,tt} &= u_{1,tt} - u_{2,tt} \\ c^2 w_{,xx} &= c^2 u_{1,xx} - c^2 u_{2,xx} \\ \implies w_{,tt} &= c^2 w_{,xx}\end{aligned}$$

So  $w$  solves the wave equation.

$$\begin{aligned}w(x, 0) &= u_1(x, 0) - u_2(x, 0) \\ &= \phi(x) - \phi(x) = 0\end{aligned}$$

and similarly

$$w_{,t}(x, 0) = 0$$

Define energy

$$E = \frac{1}{2} \int_{-\infty}^{\infty} (w_{,t}^2 + c^2 w_{,x}^2) dx$$

at  $t = 0, E = 0$ . In general, since  $E$  is conserved,  $E = 0$  at all times. But the integrand is positive semi-definite (sum of two squares) so

$$w_{,t} \equiv 0 \quad \text{and} \quad w_{,x} \equiv 0 \quad \forall (x, t)$$

meaning  $w$  is a constant and because  $w(x, 0) = 0$ , it follows  $w \equiv 0$ , so  $u_1 \equiv u_2$  everywhere.  $\square$

**10.2 Diffusion Equation**

$$u_{,t} = D u_{,xx}$$

Book uses

$$u_{,t} = k u_{,xx}$$

$D$  (or  $k$ ) is a positive constant called the diffusivity. We will solve the diffusion equation on

a finite interval  $0 < x < L$  with boundary conditions

$$u(0, t) = a(t)$$

$$u(L, t) = b(t)$$

I know the value of  $u$  on the boundaries and with initial conditions

$$u(x, 0) = g(x),$$

another known function. This equation has a maximum principle.

**Claim:** If  $u$  solves this diffusion equation, on a closed domain:

$$(x, t) \in [0, L] \times [0, T]$$

then

The maximum value of  $u$  is attained either at  $x = 0$ ,  $x = L$  or at  $t = 0$

$$u \leq \max\{g(x), a(t), b(t)\}$$

Say max value of  $u$  is attained on the parabolic boundary (either in initial data, or in boundary data)

Interpretation: If I start with matter unevenly distributed on a line segment.

If matter is introduced at end of interval, then highest density is at the end. Highest density is in boundary condition.

**Proof of maximum principle.** Assume that the max value is attained not at the parabolic boundary, i.e. at some  $(x_0, t_0)$ , which is a local maximum. So  $u_t = 0$ ,  $u_x = 0$  at  $(x_0, t_0)$  and  $u_{xx} \leq 0$ .

But

$$\begin{aligned} u_t &= Du_{xx} \\ 0 &\leq 0 \end{aligned}$$

So we have a contradiction (almost). □

# 11 Apr 20, 2022

## 11.1 Diffusion Equation (Cont'd)

**Proof of maximum principle (Cont'd).** We want to choose  $w$  so that

$$w_{,t} - Dw_{,xx} < 0$$

then

$$\underbrace{u_{\varepsilon,t} - Du_{\varepsilon,xx}}_{\geq 0 \text{ at global max}} = \varepsilon \underbrace{(w_{,t} - Dw_{,xx})}_{< 0}$$

leads to a contradiction at the global max. We need  $w \geq 0$  and  $w_{,t} - Dw_{,xx} < 0$ . E.g.

$$w = x^2 \leftarrow \text{the one we will use}$$

$$w = e^{-t}$$

Hence,

$$u_{\varepsilon} \equiv u + \varepsilon x^2$$

has its global max on the parabolic boundary.

$$\begin{aligned} u \leq u_{\varepsilon} &\leq \max_{(x,t) \in \text{parabolic boundary}} = \max_{(x,t) \in \text{parabolic boundary}} (u + \varepsilon x^2) \\ &\leq \max_{(x,t) \in \text{p.b.}} (u + \varepsilon L^2) \end{aligned}$$

because  $x^2 \leq L^2$

$$u \leq \max_{(x,t) \in \text{p.b.}} + \varepsilon L^2 \quad \forall \varepsilon > 0$$

Let  $\varepsilon$  become arbitrary small (we can do this because our inequalities hold  $\forall \varepsilon > 0$ )

$$u \leq \max_{(x,t) \in \text{p.b.}} u$$

which is the **Maximum Principle**. □

The max principle can be used to prove uniqueness of solutions because:

1.  $u$  also must obey a minimum principle. If  $u$  solves the diffusion equation, then so does  $v = -u$ . Hence,

$$\begin{aligned} \max_{(x,t) \in [0,L] \times [0,T]} &= \max_{(x,t) \in \text{p.b.}} \\ \max_{(x,t) \in [0,L] \times [0,T]} (-u) &= \max_{(x,t) \in \text{p.b.}} (-u) \\ \not\leftarrow \min_{(x,t) \in [0,L] \times [0,T]} &= \not\leftarrow \min_{(x,t) \in \text{p.b.}} (u) \end{aligned}$$

2. Suppose we have two solutions  $u_1, u_2$  of the diffusion equation with some boundary conditions and initial conditions.

$$u_{i,t} = Du_{i,xx} \quad i = 1, 2$$

and

$$\begin{cases} u_i = g(x) & \text{for } t = 0 \\ u_i = a(t) & \text{for } x = 0 \\ u_i = b(t) & \text{for } x = L \end{cases}$$

define  $w \equiv u_1 - u_2$ .

$$w_t = Dw_{,xx}$$

$$\begin{cases} w = 0 & \text{for } t = 0 \\ w = 0 & \text{for } x = 0 \\ w = 0 & \text{for } x = L \end{cases}$$

$$\max_{(x,t) \in [0,L] \times [0,T]} w = \max_{\text{p.b.}} w = 0$$

$$w \leq 0 \quad \text{by max principle}$$

$$\min_{(x,t) \in [0,L] \times [0,T]} w = \min_{\text{p.b.}} w = 0$$

$$w \geq 0$$

So  $w \equiv 0$  everywhere and  $u_1 = u_2$  so solution is unique.

## 11.2 The Source or Fundamental Solution or Green's Function Solution of the Diffusion Equation

We have

$$u_t = Du_{,xx} \quad x \in \mathbb{R}$$

with initial condition

$$u(x, 0) = \phi(x)$$

Ansatz: The density  $u(x, t)$  will have the same shape at all times, but is transformed by being stretched in the  $x$ -direction and in the  $y$ -direction.

# 12 Apr 22, 2022

## 12.1 The Source or Fundamental Solution or Green's Function Solution of the Diffusion Equation (Cont'd)

We have

$$u_{,t} = Du_{,xx} \quad x \in \mathbb{R}, t > 0$$

$$u(x, 0) = \phi(x) \quad t > 0$$

We started by asking what happens if all mass is initially at  $x = 0$ .

Hypothesize that  $u(x, t)$  has the same shape at different times, but that its height and width change.

$$u(x, t) = \mathcal{H}(t)f\left(\frac{x}{W(t)}\right)$$

Where  $\mathcal{H}(t)$  is how much function is dilated in the  $y$ -direction, and  $x/W(t)$  is the same function, dilated by different amounts  $W$ , at different times.

Define a new variable  $\eta \equiv x/W(t)$ .

$$u(x, t) = \mathcal{H}(t)f(\eta)$$

I want to rewrite the diffusion equation in terms of  $\eta, t$ .

$$(x, t) \mapsto (\eta, t)$$

$$\begin{aligned} \left(\frac{\partial}{\partial x}\right)_t &= \left(\frac{\partial t}{\partial x}\right)_t \left(\frac{\partial}{\partial t}\right)_\eta + \left(\frac{\partial \eta}{\partial x}\right)_t \left(\frac{\partial}{\partial \eta}\right)_t \\ &= 0 \cdot \left(\frac{\partial}{\partial t}\right)_\eta + \frac{1}{W} \left(\frac{\partial}{\partial \eta}\right)_t \\ \left(\frac{\partial}{\partial t}\right)_x &= \left(\frac{\partial t}{\partial t}\right)_x \left(\frac{\partial}{\partial t}\right)_\eta + \left(\frac{\partial \eta}{\partial t}\right)_x \left(\frac{\partial}{\partial \eta}\right)_t \\ &= (1) \left(\frac{\partial}{\partial t}\right)_\eta - \frac{\eta \dot{W}}{W} \left(\frac{\partial}{\partial \eta}\right)_t \end{aligned}$$

$$\eta = x/W \implies \left( \frac{\partial \eta}{\partial t} \right) = -\frac{x}{W^2} \dot{W} \\ = -\eta \frac{\dot{W}}{W}$$

where  $\dot{W} \equiv \frac{dW}{dt}$ . For  $u = Hf(n)$ ,

$$u_{,t} \equiv \dot{H}f - \frac{\eta \dot{W}}{W} \cdot Hf'$$

where  $\dot{H} = \frac{dH}{dt}$ .

$$Du_{,xx} = \frac{D}{W^2} Hf''$$

diffusion equation implies

$$\dot{H}f - \frac{\eta \dot{W}}{W} Hf' = \frac{DHf''}{W^2} \quad (12.1)$$

I went from a PDE in  $(x, t)$  to 3 unknown functions  $H(t), W(t), f(n)$ . We can turn the diffusion PDE into an ODE, by choosing  $H$  and  $W$  carefully. Compare terms:

$$-\eta \frac{\dot{W}H}{W} f' = - \underbrace{nf'}_{\text{function of } \eta} \frac{\dot{W}H}{W} \\ \underbrace{\frac{DH}{W^2}}_{\text{function of } t} \underbrace{f''}_{\text{function of } \eta}$$

Choose  $W$  so that:

$$\frac{DH}{W^2} = \frac{\dot{W}H}{W} \\ D = \dot{W}W \\ = \frac{d}{dt} \left( \frac{1}{2} W^2 \right) \\ Dt = \frac{1}{2} W^2 \\ W(t) = \sqrt{2Dt}$$

Choose  $H$  so that

$$\dot{H} = \frac{DH}{W^2} = \frac{H}{2t}$$

given  $W(t) = \sqrt{2Dt}$ .

$$\begin{cases} \frac{\dot{H}}{H} = \frac{1}{2t} \\ \log(H) = \frac{1}{2} \log(t) \end{cases} \implies H = t^{1/2}$$

A hand wavy way to find  $H(t)$  and  $W(t)$ .

$$u_{,t} = Du_{,xx}$$

We want to estimate the size of the terms in the equation.

$$u_{,t} \sim H$$

where  $\sim$  means ball-park estimate.

$$u_{,x} \sim \frac{H}{W}, \quad u_{,xx} \sim \frac{H}{W^2}$$

for equality we need:

$$u_{,t} = Du_{,xx}$$

$$\frac{H}{t} \sim \frac{DH}{W^2} \implies \begin{cases} W^2 \sim Dt \\ W \sim \sqrt{Dt} \end{cases}$$

but  $H$  can not be estimated from the equation. We also need an initial condition. Recall that the equation represents conservation of mass.

$$\underbrace{\frac{d}{dt} \int_{-\infty}^{\infty} u \, dx}_{\text{time rate of change of total mass}} = \int_{-\infty}^{\infty} \frac{\partial u}{\partial t} dx = D \int_{-\infty}^{\infty} \frac{\partial^2 u}{\partial x^2} dx$$

$$= - \left[ D \frac{\partial u}{\partial x} \right]_{-\infty}^{\infty} = 0$$

The total mass is constant, let

$$\int_{-\infty}^{\infty} u \, dx = 1$$

Handwavy:  $HW \sim 1$ . Which is height  $\times$  width of function

$$H \sim \frac{1}{W}$$

$$H \sim \frac{1}{\sqrt{Dt}}$$

Careful route:

$$\int_{-\infty}^{\infty} u \, dx = 1$$

$$\int_{-\infty}^{\infty} H(t) f(\eta) dx = 1$$

$$= HW \int_{-\infty}^{\infty} f(\eta) \eta$$

$$\left( \frac{\partial \eta}{\partial x} \right)_t = \frac{1}{W}$$

$$W d\eta = dx$$

$$\implies HW = \frac{1}{\int_{-\infty}^{\infty} f(\eta) d\eta}$$

$H \propto \frac{1}{W}$  because the integral is just a number.

Now assume

$$H(t) = \frac{1}{\sqrt{Dt}}, \quad W(t) = \sqrt{Dt}$$

Look for a solution of the equation with

$$u(x, t) = \underbrace{\frac{1}{\sqrt{Dt}}}_H f\left(\underbrace{\frac{x}{\sqrt{Dt}}}_{\eta=x/W}\right)$$

for some function  $f$ . Substitute into Equation 12.1:

$$\begin{aligned} \dot{H} &= \frac{d}{dt} \left( \frac{1}{\sqrt{Dt}} \right) = -\frac{1}{2\sqrt{Dt^3}} \\ -\frac{1}{2\sqrt{Dt^3}}f - \frac{1}{2t\sqrt{Dt}}\eta f' &= \\ -\frac{\eta \dot{W}}{W} H f' &= (-\eta f') \left( \frac{\dot{W} H}{W} = \frac{1}{2t} \frac{1}{\sqrt{Dt}} \right) \end{aligned}$$

# 13 Apr 25, 2022

## 13.1 Continuing the Fundamental Solution of Diffusion Equation

We solve:

$$u_t = Du_{xx}$$

assume all mass is initially at  $x = 0$  and that the solution is self-similar; it has the same but scaled in height and width at all times.

$$u(x, t) = H(t)f\left(\frac{x}{W(t)}\right)$$

$H$  is height,  $W$  is width.

$$u_t = Du_{xx}$$

1.  $\frac{H}{t} \sim \frac{DH}{W^2} \implies W \sim \sqrt{Dt}$
2. The total mass is conserved:

$$HW \sim 1 \implies H \sim \frac{1}{\sqrt{Dt}}$$

Hence I look for a solution of form:

$$u(x, t) = \frac{1}{\sqrt{Dt}} f\left(\underbrace{\frac{x}{\sqrt{Dt}}}_{\eta}\right)$$

see books by G.I. Barenblatt.

From last class:

$$\begin{aligned}
 \left(\frac{\partial}{\partial t}\right)_x &\rightarrow \left(\frac{\partial}{\partial t}\right)_\eta + \left(\frac{\partial \eta}{\partial t}\right)_x \left(\frac{\partial}{\partial \eta}\right)_t \\
 &= \left(\frac{\partial}{\partial t}\right)_\eta - \frac{\eta}{2t} \left(\frac{\partial}{\partial \eta}\right)_t \\
 \left(\frac{\partial}{\partial x}\right)_t &\rightarrow \frac{1}{\sqrt{Dt}} \frac{\partial}{\partial \eta} \\
 u &\equiv \frac{1}{\sqrt{Dt}} f(\eta)
 \end{aligned}$$

LHS:

$$\begin{aligned}
 u_{,t} &= -\frac{1}{2\sqrt{Dt^3}} f - \frac{\eta}{2\sqrt{Dt^3}} f' \\
 Du_{,xx} &= \frac{D}{\sqrt{Dt}(Dt)} f'' \\
 \Rightarrow -\frac{1}{2\sqrt{Dt^3}} f - \frac{\eta}{2\sqrt{Dt^3}} f' &= \frac{1}{\sqrt{Dt^3}} f'' \\
 -\frac{1}{2} f - \frac{\eta}{2} f' &= f''
 \end{aligned}$$

thus is an ODE in  $\eta$ . Boundary conditions are  $u \rightarrow 0$  as  $x \rightarrow +\infty$ , or equivalently,  $f \rightarrow 0$  as  $\eta \rightarrow \pm\infty$ . Notice  $u$  is even in  $x$ ,  $f$  is an even function of  $\eta$ .

$$-\frac{1}{2}(\eta f)' = f'' \quad (13.1)$$

$$c - \frac{1}{2}\eta f' = f'$$

since  $f$  is even,  $f'(0) = 0$ .

$$\Rightarrow c - 0 = 0 \Rightarrow c = 0$$

Hence

$$\begin{aligned}
 -\frac{1}{2}\eta f &= f' \\
 -\frac{1}{2}\eta &= \frac{f'}{f} \\
 c - \frac{1}{4}\eta^2 &= \log |f| \\
 \Rightarrow f &= C e^{-1/4\eta^2}
 \end{aligned}$$

$C$  a constant of integration.  $f \rightarrow 0$  as  $\eta \rightarrow \pm\infty$ . We require:

$$\int_{-\infty}^{\infty} u(x, t) dx = 1 \quad \forall t$$

Notice

$$\eta = \frac{x}{\sqrt{Dt}} \implies d\eta = \frac{dx}{\sqrt{Dt}}$$

So

$$\int_{-\infty}^{\infty} \frac{1}{\sqrt{Dt}} f(\eta) \cdot \sqrt{Dt} d\eta = 1$$

$$\int_{-\infty}^{\infty} C_1 e^{-1/4\eta^2} d\eta = 1$$

$$C_1 = \frac{1}{\int_{-\infty}^{\infty} e^{-1/4\eta^2} d\eta}$$

**Recall 13.1** (A fact about the normal distribution)

$$\frac{1}{\sqrt{2\pi\sigma^2}} \int_{-\infty}^{\infty} e^{-\frac{x^2}{2\sigma^2}} dx = 1$$

$$\implies \int_{-\infty}^{\infty} e^{-\frac{x^2}{2\sigma^2}} dx = \sqrt{2\pi\sigma^2}$$

Hence

$$C_1 = \frac{1}{\sqrt{4\pi}}$$

$$u(x, t) = \frac{1}{\sqrt{4\pi Dt}} e^{-\frac{x^2}{4Dt}}$$

is a solution of the diffusion equation.

at  $t = 0$ ,

$$u(x, 0) = \begin{cases} 0 & \text{except at } x = 0 \\ \infty & \text{at } x = 0 \end{cases}$$

$$\int_{-\infty}^{\infty} u(x, 0) dx = 1$$

We call  $u(x, 0), \delta(x)$  the Dirac  $\delta$ -function.

## 13.2 Solving the Diffusion Equation for Arbitrary Initial Conditions

Idea # 1: Suppose we start with all of our mass at  $x = 1$ .

We expect solution to be translated by +1,

$$u(x, t) = \frac{1}{\sqrt{4\pi Dt}} e^{-\frac{(x-1)^2}{4Dt}}$$

Solution for any starting location  $y$ , is:

$$S(x - y, t) = S(x, t; y) = \frac{1}{\sqrt{4\pi Dt}} e^{-\frac{(x-y)^2}{4Dt}}$$

Idea # 2:

Given  $u(x, 0) = \phi(x)$ , find  $u(x, t)$  by approximating  $\phi(x)$  by a set of spikes/ $\delta$ -functions.

Replace  $\phi(x)$  by a set of spikes, spacing  $\Delta x$ . Spike at  $x = x_i$ , has mass  $\phi(x_i)\Delta x$ . Solution from this spike is

$$S(x - x_i, t)\phi(x_i)\Delta x$$

add all spikes together;

$$u(x, t) = \sum_i S(x - x_i, t)\phi(x_i)\Delta x$$

let  $\Delta x \rightarrow 0$ ;

$$u(x, t) = \int_{-\infty}^{\infty} S(x - y, t)\phi(y)dy$$

# 14 Apr 27, 2022

## 14.1 Solving the Diffusion Equation for Arbitrary Initial Conditions (Cont'd)

Recall from last class, we derived a solution

$$\left. \begin{array}{l} S(x, t; y) \\ S(x - y, t) \end{array} \right\} = \frac{1}{\sqrt{4\pi Dt}} e^{-(x-y)^2/4Dt}$$

Total mass 1, with all mass initially concentrated at  $y$ . We claim that if the initial condition is  $u(x, 0) = \phi(x)$ , the solution is:

$$u(x, t) = \int_{-\infty}^{\infty} S(x - y, t) \phi(y) dy \quad (14.1)$$

Let's prove this is truly the solution.

$$\begin{aligned} u_{,t} - Du_{,xx} &= \left( \frac{\partial}{\partial t} - D \frac{\partial^2}{\partial x^2} \right) \int_{-\infty}^{\infty} S(x - y, t) \phi(y) dy \\ &= \int_{-\infty}^{\infty} \underbrace{\left( \frac{\partial}{\partial t} S(x - y, t) - D \frac{\partial^2}{\partial x^2} S(x - y, t) \right)}_{0 \text{ because } S \text{ solves PDE}} \phi(y) dy \end{aligned}$$

We also need to show the initial condition is satisfied. I.e. we need  $u(x, 0) = \phi(x)$ . Want to substitute into equation 14.1:

$$\int_{-\infty}^{\infty} \underbrace{S(x - y, 0)}_{-\frac{\partial}{\partial y} \mathcal{Q}(x-y)} \phi(y) dy = [-\mathcal{Q}(x - y) \phi(y)] \Big|_{-\infty}^{\infty} + \int_{-\infty}^{\infty} \mathcal{Q}(x - y) \phi'(y) dy$$

We will use integration by parts to evaluate the integral.

**Recall 14.1**  $S(x, 0) = 0$  except at  $x = 0$ .

$\int_{-\infty}^{\infty} S(x, 0) dx = 1$  because mass is conserved.

This implies

$$\int_I S(x, 0) dx = 1$$

if  $I$  is any interval containing  $x = 0$ . Define

$$\mathcal{Q} = \int_{-\infty}^x S(\tilde{x}, 0) d\tilde{x} = \begin{cases} 0 & \text{if } x < 0 \\ 1 & \text{if } x > 0 \end{cases}$$

this is called the **Heaviside function**.

$$\text{integral} = [0 + \phi(-\infty)] + \int_{-\infty}^x \phi'(y) dy$$

because

$$\mathcal{Q}(x - y) = \begin{cases} 1 & \text{if } x > y \\ 0 & \text{if } x < y \end{cases}$$

$$u(x, 0) = \text{integral} = \phi(-\infty) + \phi(x) - \phi(-\infty) = \phi(x)$$

So Equation 14.1 satisfies the initial condition.

## 14.2 Midterm Review Topics

Need to be able:

- Calculate partial derivatives, e.g.

$$\frac{\partial}{\partial y} \sin(x - y) \cos(x + y)$$

- Linear first order PDEs
  - Recognize them
  - Geometric interpretation of characteristics for PDEs of form:

$$a(x, y)u_{,x} + b(x, y)u_{,y} = 0$$

with equation of characteristics

$$\frac{dy}{dx} = \frac{b}{a}$$

E.g.

$$xu_{,x} + yu_{,y} = 0$$

$$\frac{dy}{dx} = \frac{y}{x}$$

$$\int \frac{1}{y} dy = \int \frac{1}{x} dx$$

$$\log |y| = \log |x| + C$$

$$\implies \frac{y}{x} = \pm e^C \implies f\left(\frac{y}{x}\right) = u(x, y)$$

is a solution.

If I am given  $u(x, 1) = e^x$ , how much of the  $x$ - $y$  plane can I find the solution on?  
 I can find  $u(x, y)$  for all  $y > 0$  (over whole upper half plane)

I can not fill in the solution for  $y \leq 0$ .

For  $y > 0$

$$u(x, y) = f\left(\frac{y}{x}\right)$$

$$f\left(\frac{1}{x}\right) = e^x$$

from auxiliary condition.

$$f(z) = e^{1/z}$$

$$u(x, y) = f\left(\frac{y}{x}\right) = e^{x/y}$$

- Interpreting PDEs:

$$\frac{\partial u}{\partial t} + \frac{\partial q}{\partial x} = 0$$

what is  $u$ , what is  $q$ , what does this PDE represent?

$u$ : amount of shift at  $(x, t)$  (density)

$q$ : (flow rate) amount of shift passing  $x$  in unit time.

–  $q = cu$  transport equation

–  $q = -D \frac{\partial u}{\partial x}$  diffusion equation

$-D \frac{\partial u}{\partial x} = 0$ ? at  $(0, t)$  what does this mean? closed end

$u = 0$ ?,  $u(0, t)$  no bacteria at  $x = 0$

- Classifying PDEs as elliptic, hyperbolic, parabolic

$$a_{11}u_{,xx} + 2a_{12}u_{,xy} + a_{22}u_{,yy} + \dots$$

- D'Alembert's Solution

$$u(x, t) = \begin{cases} \frac{1}{2}(\phi(x+ct) + \phi(x-ct)) + \frac{1}{2c} \int_{x-ct}^{x+ct} \psi(y) dy \\ f(x+ct) + g(x-ct) \end{cases}$$

- Domain of dependence and region of influence (e.g. Q3 of homework 4)
